Q1. What is the optimal value of alpha for ridge and lasso regression? What will be the changes in the model if you choose double the value of alpha for both ridge and lasso? What will be the most important predictor variables after the change is implemented?

The optimum value of alpha for ridge is 1 and lasso is 0.0009.

The alpha value is small and doubling it does not affect both the models

Most important predictor variables remains the same after the change in alpha value is implemented

Q2. You have determined the optimal value of lambda for ridge and lasso regression during the assignment. Now, which one will you choose to apply and why?

Q3. After building the model, you realised that the five most important predictor variables in the lasso model are not available in the incoming data. You will now have to create another model excluding the five most important predictor variables. Which are the five most important predictor variables now?

Q4. How can you make sure that a model is robust and generalisable? What are the implications of the same for the accuracy of the model and why?
